1.1 Overview

This application can be controlled from an external controller (PC) by remote control commands using the MS269x Series, MS2830A, and MS2850A Signal Analyzer. The remote control commands are defined by the SCPI format.

1.1.1 Interface

This instrument has GPIB, Ethernet, and USB interfaces for remote control. Those interfaces cannot be used at the same time.

The interface is automatically determined when a command is received at the start of communication. This instrument enters the remote state after the interface has been determined. At remote-interface operation, the front panel  lamp lights; the lamp is off at local-interface operation.

Refer to the “MS2690A/MS2691A/MS2692A and MS2830A/MS2840A/MS2850A Signal Analyzer manual (Mainframe Remote Control)” for more details of the basic operations for remote control, such as interface setting.

1.1.2 Controlled Application

Two types of the remote control commands can be used with this instrument: commands that are commonly applied to this instrument or all the applications (hereinafter, referred to as, “Common command”), and the other commands unique to a specific application. Common commands can be executed at any time and do not depend on the currently controlled application. However, a command unique to a specific application can be executed at the controlled application. If it is executed at another application, the command is not executed or an error occurs.

In this instrument, multiple applications can be activated at the same time. Only one application resource can be executed per piece of hardware at one time. This application measures an input signal by using the resource of RF input. Thus, this application cannot be executed at the same time with another application using the same resource such as the signal analyzer function. In order to execute a function unique to the application by using remote control, you need to select this application while it has been activated. Furthermore, this application can be executed at the same time with another application that uses by itself a resource not used by this application, such as the Vector Signal Generator Option.

1.2 Basic Flow of Control

This section describes the basic remote control command programming operations for measuring GSM/EDGE signals.

Figure 1.2-1 shows the control flow for a basic test. Note the parameter settings for the measurement, type of measurement function, and measurement execution order, although the measurement order can be changed.

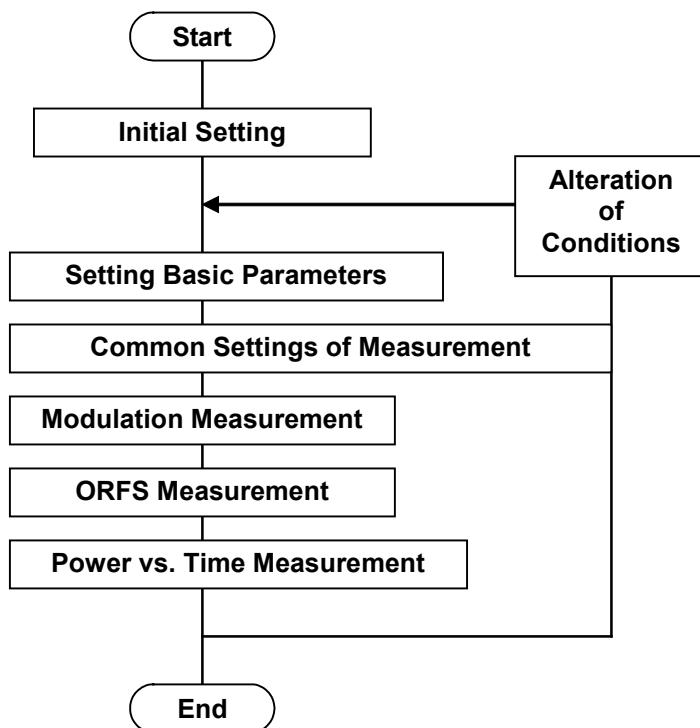

Figure 1.2-1 Basic Test Flow

1.3 Native Mode

In this instrument, the syntax/format types of the remote control commands are defined as “Language mode”. The language mode has two modes: SCPI and Native.

(1) SCPI Mode

The SCPI mode processes commands conforming to the syntax/format defined in SCPI (ver1999.0). For programming, you can use the character string in long/short form format and can omit angled bracket ([]) definition character strings.

On the Configuration screen, the SCPI mode is automatically set after transmitting command `SYST:LANG SCPI`.

(2) Native Mode

The Native mode processes commands that are in this instrument’s own definition type. Unless otherwise specified, the character string of a command header is fixed. If application commands are defined only by the SCPI mode, character strings converted according to the conversion rules are the commands in the Native mode.

Note:

The `STATus:QUEStionable` and `STATus:OPERation` registers cannot be used, even when the corresponding commands are converted to Native-mode commands according to the conversion rules.

On the Configuration screen, the Native mode is automatically set after transmitting `SYST:LANG NAT`.

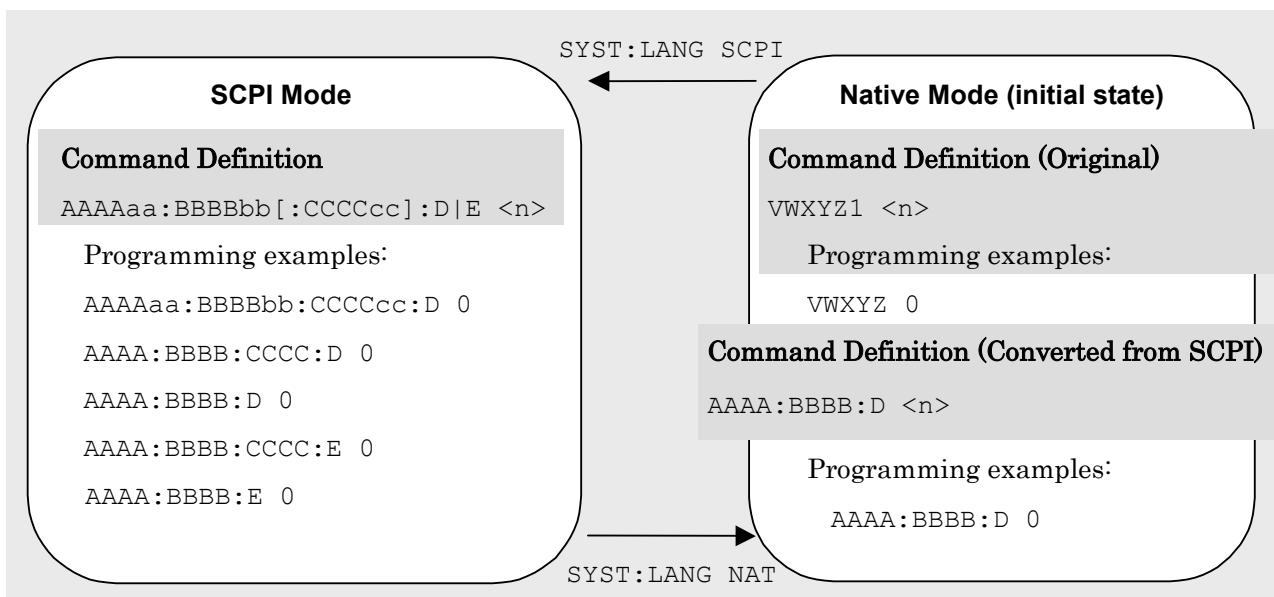

Figure 1.3-1 SCPI and Native modes

This application is only defined as the SCPI mode commands. You need to follow the conversion rules below in order to control this application by using the Native mode.

Conversion Rules:

- (1) Move the numeric parameter in the program header of an SCPI command before the argument. Delete a numeric parameter which only has one value and can be deleted. Describe the argument if it cannot be deleted.
- (2) Use the first node if multiple ones can be selected.
- (3) Delete those layers which can be deleted.
- (4) Alter all the long-formed characters into short-formed ones.
- (5) Delete the colon mark (“:”) at the head.

Example 1:

To convert :CALCulate:MARKer[1] | 2 [:SET] :CENTer into a Native mode command.

- (1) Move the numeric parameter in the program header before the argument.

```
:CALCulate:MARKer[1]|2[:SET]:CENTer
↓
:CALCulate:MARKer[:SET]:CENTer <integer>
(A numeric value(1 or 2) is put <integer>.)
```

- (2) Delete the layers which can be deleted.

```
:CALCulate:MARKer[:SET]:CENTer <integer>
↓
:CALCulate:MARKer:CENTer <integer>
```

- (3) Alter all the long-formed characters into short-formed ones.

```
:CALCulate:MARKer:CENTer <integer>
↓
:CALC:MARK:CENT <integer>
```

- (4) Delete the colon mark (“:”) at the head.

```
:CALC:MARK:CENT <integer>
↓
CALC:MARK:CENT <integer>
```

Example 2:

To convert [:SENSe] :BPOWer | :TXPower [:STATE] ? into a Native mode command.

- (1) Use the first node if multiple ones can be selected.

[:SENSe] :BPOWer | :TXPower [:STATE] ?

↓

[:SENSe] :BPOWer [:STATE] ?

- (2) Delete the layers which can be deleted.

[:SENSe] :BPOWer [:STATE] ?

:BPOW ?

↓

BPOW ?

Example 3:

To convert :FETCH:EVM[n] ? into a Native mode command.

- (1) Move the numeric parameter in the program header before the argument.

:FETCH:EVM[n] ?

↓

:FETCH:EVM? <integer>

(A numeric value is put in <integer>.)

- (2) Alter all the long-formed characters into short-formed ones.

:FETCH:EVM? <integer>

In this application, DEFault, MINimum, and MAXimum can be used for the following parameters:

<numeric_value>

<freq>

<real>

<rel_power>

<integer>

<rel_ampl>

<time>
